Western Washington University April 7, 2023

Question 1

a)

I would choose to test if the two population means where equal, ie,

 $H_0: \mu_1 = \mu_2$ $H_a: \mu_1 \neq \mu_2$

b)

	Location 1	Location 2
Sample Mean	$\bar{y}_1 = 2980$	$\bar{y}_2 = 3205$
Sample Standard Deviation	$S_1 = 1140$	$S_2 = 963$
Sample Size	$n_1 = 40$	$n_2 = 40$
Sample Variance	$S_1^2 = 1299600$	$S_2^2 = 927369$

At significance level $\alpha=0.10$. With degrees of freedom $v=(n_1+n_2)-2=40+40-2=78$.

$$S_p = \frac{(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2}{n_1 + n_2 - 2}$$

$$= \frac{(40 - 1) \times 129960 + (40 - 1) \times 927369}{40 + 40 - 2}$$

$$= 528664.5$$

$$t = \frac{y_1 - \bar{y_2}}{S_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$
$$= \frac{2980 - 3205}{528664.5 \sqrt{\frac{1}{40} + \frac{1}{40}}}$$
$$\approx -0.0019$$

The Test Statistic $t_{\alpha/2,v} = t_{.05,78} \approx 1.671$. Note that $t < t_{.05,78}$ and is not in the critical region. Therefore, there is not enough statistical evidence to support the population means being unequal, that is, $\mu_1 \neq \mu_2$.

c)

The P-value can be obtained in R using the following code.

Listing 1: Calculating the P-value for a t value # define the t-statistic t <- -0.0019 # calculate the P-value for a two-tailed t-test p_value <- 2 * pt(t, df = 78, lower.tail = FALSE) # print the P-value p_value

The following code shows that the P-value = 1.001511.

d)

A 90% confidence interval for the difference in the true mean distance between the two populations is: interval for the difference in the true mean distance between

$$(y_1 - \bar{y}2) \pm t\frac{\alpha}{2}, 78 * S_p * \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}$$

$$\pm 1.671 * 528664.5 * \sqrt{\frac{1}{40} + \frac{1}{40}}$$

$$\pm 197533.8$$

$$(-197785.8, 197308.8)$$

This confidence interval contains zero, which is consistent with conclusion reported above.

Question 2

First we note that,

$$t = \frac{\bar{X} - \mu_0}{S/\sqrt{n}} \sim N(0, 1)$$

Then we can derive that,

$$1 - \alpha = P(-t_{\alpha,n-1} \le \frac{\bar{X} - \mu_0}{S/\sqrt{n}} \le t_{\alpha,n-1})$$

$$= P(-t_{\alpha,n-1} \frac{S}{\sqrt{n}} \le \bar{X} - \mu_0 \le t_{\alpha,n-1} \frac{S}{\sqrt{n}})$$

$$= P(-\bar{X} - t_{\alpha,n-1} \frac{S}{\sqrt{n}} \le -\mu_0 \le -\bar{X} + t_{\alpha,n-1} \frac{S}{\sqrt{n}})$$

$$= P(\bar{X} + t_{\alpha,n-1} \frac{S}{\sqrt{n}} \ge \mu_0 \ge \bar{X} - t_{\alpha,n-1} \frac{S}{\sqrt{n}})$$

$$= P(\bar{X} - t_{\alpha,n-1} \frac{S}{\sqrt{n}} \le \mu_0 \le \bar{X} + t_{\alpha,n-1} \frac{S}{\sqrt{n}})$$

$$= P(\bar{X} - t_{\alpha,n-1} \frac{S}{\sqrt{n}} \le \mu_0 \le \bar{X} + t_{\alpha,n-1} \frac{S}{\sqrt{n}})$$

Therefore, the confidence interval for one population mean μ in the case where the population variance σ^2 is unknown can be described as

$$\bar{X} \pm t_{\alpha, n-1} \frac{S}{\sqrt{n}}$$

Question 3

The P-value can be obtained in R using the following code, where t_0 varies.

Listing 2: Calculating the P-value for a t_0 value

```
# Define the t_0 value, degrees of freedom, and tail of the distribution \mathbf{t}_{-0} < 2.48 \mathbf{df} < 10 \mathbf{tail} < 2 # Calculate the P-value using the "pt" function \mathbf{p}_{-}\mathbf{val} < \mathbf{pt}(\mathbf{t}_{-0}, \mathbf{df}, \mathbf{tail}) # Print the P-value \mathbf{print}(\mathbf{p}_{-}\mathbf{val})
```

a)

When $t_0 = 2.48$, the P-value is 0.637.

b)

When $t_0 = 3.55$, the P-value is 0.869.

c)

When $t_0 = 2.00$, the P-value is 0.478.

Question 4

a)

Test

Null hypothesis H_0 : μ = 225 Alternative hypothesis H_1 : μ > 225

7-Value P-Value 0.67 0.257

Figure 1: The output of the 1-sample t test from Minitab.

 H_0 : The mean repair time is 225 hours.

 H_a : The mean repair time exceeds 225 hours.

b/c)

Since the p-value (0.257) is greater than the significance level (0.05), we fail to reject the null hypothesis. That is, there is not enough statistical evidence to support that the mean repair time exceeds 225 hours.

d)

Descriptive Statistics

				95% Lower Bound	
	Ν	Mean	StDev	SE Mean	for μ
	16	241.5	98.7	24.7	198.2

μ: population mean of Hours

Figure 2: The Descriptive Statistics of the 1-sample t test from Minitab.

Question 5

- **a**)
- b)
- **c**)
- d)
- **e**)

Question 6

Question 7

We can estimate the sample mean by observing the values at the 50^{th} percentile. This gives us: $\stackrel{\sim}{\mu}=98.6$

We can estimate the sample standard deviation by taking the reciprocal of the slope of the best-fit line. This can be approximated as: $\overset{\sim}{\sigma}=1/0.27=3.7$
